Abstract

A novel and selective method for the fast determination of trace amounts of Cr (III) ions in water samples has been developed. Method has been developed for preconcentration of Cr on organic-solution-processable functionalized-graphene (SPFGraphene) adsorbent in the pH range 5.0 – 10.0, prior to its spectrophotometric determination, based on the oxidation of bromopyrogallol red at \( \lambda = 517 \) nm. This method makes it possible to quantitize Cr in the range of \( 4.2 \times 10^{-9} \) to \( 2.3 \times 10^{-7} \) M, with a detection limit (S/N = 3) of \( 1.42 \times 10^{-9} \) M. This procedure has been successfully applied to determine the ultra-trace levels of Cr in the environmental samples, free from the interference of some diverse ions. The precision, expressed as relative standard deviation of three measurements is better than 3.0%.

Key words: Cr (III) ; SPE; AAS ; organic-solution-processable functionalized-graphene (SPFGraphene)

1. Introduction

Toxicological studies have proved that the degree of toxicity of an element directly depends on the species in which it is present. Cr(III) is considered as an essential micronutrient for humans and mammals in order to maintain glucose metabolism, whereas Cr(VI) is a potentially carcinogenic agent[1]. Cr(III) at trace concentrations acts as both a micronutrient and a toxicant in marine and fresh water systems [2-5]. This element is needed by plants at only very low levels and is toxic at higher levels. At these levels, Cr(III) can bind to the cell membrane and hinder the transport process through the cell wall. Cr(III) at nearly 40 ng mL\(^{-1}\) is required for normal metabolism of many living organisms[6]. On the other hand, Cr(III) is an important element in many industries. Thus, the development of new methods for selective separation, concentration and determination of it in sub-micro levels in different industrial, medicinal and environmental samples is of continuing interest. The determination of Cr(III) is usually carried out by flame and graphite furnace atomic absorption spectrometry (AAS) [7], as well as spectrometric methods [10].

Solid phase extraction (SPE) methods are the best alternatives for traditional classic methods due to selective removal of trace amounts of metal ions from their matrices. Solid phase extraction determinations can be carried out on different efficient ways. One of the most appropriate performances features of SPE is achieved by using octadecyl silica membrane disks. SPE reduce the use of toxic solvent, disposal costs, and extraction time[8-11]. The octadecyl silica membrane disks involves shorter sample processing time and decreased plugging due to the large cross-sectional area of the disk and small pressure drop which allows higher flow-rates; reduced channeling resulting from the use of sorbent with smaller particle size and a greater mechanical stability of the sorbent bed[13]. In our previous attempts, we modified SPE membrane disks with suitable compounds for selective determination of chromium [14] and lead [11]. Meanwhile, other investigators have successfully utilized these sorbents for quantitative extraction and monitoring trace amounts of lead[15], copper [16], silver[19], mercury [17,19], cadmium [20], palladium [21], Ce[22] and UO\(_2\) [12].

The used ligand is new and fairly selective and will not interfere in the determination process of Cr(III). Absorption spectrophotometry method (after preconcentration) was applied for determination of Cr based on the oxidation of bromopyrogallol red at 517 nm. Various effective parameters have been evaluated, and the developed procedure has been successfully employed for the quantitation of ultra-trace amounts of Cr in water sample.

2. Material and Methods

2.1. Apparatus

The glass column with 10 mm i.d. and 200 mm height was used to make preconcentration column. An UV–Vis spectrophotometer WPA Cambridge UK (Diode Array, Model S2000) was applied for recording the absorption spectra. A spectrophotometer (Perkin-Elmer model 35) with
10 mm glass cuvette was used to measure the absorbance at a fixed wavelength. Controlling the reaction temperature was done by a water bath thermostat (Gallenkamp Griffin, BJ-240-V) and a stopwatch was used for recording the reaction time. The synthesis of the TPP-NHCO-SPFGraphene, is illustrated in Fig. 1.

2.2. Reagents
Doubly distilled water and analytical-reagent grade chemicals were used throughout.

2.2.1. Synthesis of TPP-NHCO-SPF Graphene
The first organic-solution-processable functionalized-graphene (SPFGraphene) hybrid material with porphyrins. The synthesis of the porphyrin–Graphene nanohybrid, 5-4 (aminophenyl)-10, 15, 20-triaryl porphyrin (TPP) and graphene oxide molecules covalently bonded together via an amide bond (TPP-NHCO-SPF Graphene, Scheme 1 and 2) was carried out using an amine-functionalized porphyrin (TPP-NH2) and Graphene oxide in N,N-dimethylformamide (DMF), following standard chemistry. Large-scale and water-soluble Graphene oxide was prepared by the modified Hummers method[24,25]. Results of atomic force microscopy characterization have confirmed that this graphene material can be easily dispersed at the state of complete exfoliation, which consists of almost entire single-layered Graphene sheets in H2O[24,25]. TPP-NH2 and Graphene oxide molecules are covalently bonded together by an amide bond. Much care has been taken to make sure all the unreacted TPP-NH2 has been removed using extensive solvent washing, sonication, and membrane filtration. Details are given in the Experimental part. The attachment of organic molecules to Graphene oxide has made TPP-NHCO-SPFGraphene soluble in DMF and other polar solvents[24,26].

2.2.2. Standard Cr solution
A standard solution of Cr(III), 1.0×10−3 M was prepared by dissolving 0.1111 g Cr nitrate (Merck) in water containing a drop of concentrated HCl and diluting to the mark in a 250-ml volumetric flask. All working solutions of Cr(III) were prepared by serial dilution of the stock solution.

2.2.3. Standard bromopyrogallol red solution
An aqueous solution of (1.0×10−4 M) bromopyrogallol red (Merck) was prepared by dissolving 0.0140 g bromopyrogallol red in water and diluting to the mark in a 250-ml volumetric flask. Universal buffer solutions in the range from 2.0 to 10.0 were prepared with acetate, phosphate, and borate. Glycine/HCl buffer was used for pH 1.0. Stock solutions (5.0×10−3 M) of interfering ions were prepared by dissolving suitable salts in water, hydrochloric acid or sodium hydroxide solutions.

2.3. General procedure
The column was packed with 3.0 g adsorbent and was conditioned with 1.0–2.0 ml of pH 5.0. Then, 10.0 ml of Cr solution (5.0×10−5 M) was passed through the column at 0.1 ml min−1. The analyte was eluted from the column by 1.0 ml of HCl, 1.0 M. A sample solution was prepared by pouring 0.5 ml of buffer solution (pH 1.0) in a 10.0 volumetric flask and 3.0 ml of 1.0×10−4 M bromopyrogallol red was added. The mixture diluted to ca. 8 ml with water then 1.0 ml of Cr(III) (5.0×10−5 M) (eluted solution from column) was added and the solution diluted to the mark with water. The reaction mixture as agitated and then an appropriate amount of the solution was transferred to the spectrophotometric cell and variation in absorbance was recorded for the first 0.5–5.0 min from initiation of the reaction at 517 nm. A calibration graph was plotted with absorbance change (ΔA = A5 − A0.5) versus Cr concentration.

3. Results and Discussion
Organic-solution-processable functionalized-graphene (SPFGraphene) with the following structure (Scheme 1) is a new chelating agent which can form stable complex with Cr(III). By immobilizing this tridentate bisamide ligand on microcrystalline naphthalene, Cr(III) can be adsorbed. Then desorption of Cr is carried out by using a strong inorganic acid. The Cr(III) concentrations were determined spectrophotometrically after passing solution through the column. Therefore, first the optimum conditions for spectrophotometric procedure should be studied.

3.1. Effect of variables on the determination of Cr
Bromopyrogallol red with following structure Fig. 1 is oxidized by Cr and the absorbance of the solution decreases with time, at λ = 517 nm. The change in the signal is proportional to Cr concentration. Fig. 3 shows the absorption spectra of bromopyr- ogallol red-Cr system at different times. Experiment (spectrophotometric determination) on eluted Cr solution was done at different pH values (1.0–5.0). Fig. 2 shows the effect of pH on the net absorbance (ΔA). The maximum net absorbance is at pH 1.0; whereas higher pH values cause decreasing in the signal. At higher pH values, oxidation potential of Bromopyrogallol red increases, thus the reaction rate and ΔA decreased. Therefore the pH of 1.0 was selected for this study. The influence of bromopyrogallol red concentration on the reaction rate was tested at pH 1.0 with 1.0×10−5 M, Cr(III) at 30 ◦C (Fig. 3). It can be seen that the best concentration for bromopyrogallol red is 3.0×10−5 M. At higher values the aggregation of bromopyrogallol red causes the reaction rate to be decreased. Effect of temperature on the maximum signal is studied for the range of 10–50 ◦C, under optimum conditions otherwise as previously described. Fig. 4 shows that with increasing temperature up to 30 ◦C, ΔA signal or the rate of reaction increases. So temperature was fixed at 30 ◦C. At higher temperature bromopyrogallol red can be decomposed.

3.2. Effect of variables on the preconcentration
The effect of pH on preconcentration of Cr(III) was examined in range of 1.0–10.0, and the results are shown in Fig. 5. The results show that in the pH range of 5.0–10.0, the analyte was adsorbed on microcrystalline naphthalene quantitate and the recovery was more than 90%. For pH lower than 5.0 the complex will not be formed on adsorbent (at acidic media, active sites of ligand will be protonated) and at high pH values, Cr will precipitate on the column (precipitating instead of adsorption will occur). In order to obtain the best conditions for determination after preconcentration and to prevent the precipitation of Cr (especially at high concentrations), the most acidic pH from this range of buffers (5–10), was selected.

The influence of analyte retention time was investigated by passing 10.0 ml of Cr(III) (5.0×10⁻¹⁵ M) solution in the pH 5.0 with different flowrates, and performing the experiment with the passed solution. The results show that in the higher flow rates, Cr cannot be adsorbed on microcrystalline naphthalene quantitatively. The best flow rate was selected to be 0.1 ml min⁻¹. As the Cr complex is unstable in high acidic solutions, hydrochloric acid was selected to desorb the adsorbed analyte. Fig. 6 shows that Cr(III) can be desorbed from the adsorbent by elution with 1.0 ml, HCl, 1.0 M. For investigating the ability of microcrystalline naphthalene to adsorb Cr(III) after sequential elutions, the preconcentration process was repeated for many times. It was indicated that the results were satisfactory, even by using one column for 10 times, without changing the packing. The different volumes of Cr solution, 1.0×10⁻⁸ M in the range of 10–1000 ml were passed through the column and the signal of each eluted solution was compared with calibration curve data which is achieved from determination method. The obtained signals of concentrated Cr solutions presented that a preconcentration factor of 100 can be achieved by this method. The effect of ionic strength on the sensitivity was studied. The sensitivity would be slightly changed with increasing the ionic strength of the reaction mixture.

3.3. Retention capacity of the adsorbent

The retention capacity of organic-solution-processable functionalized-graphene (SPFGraphene) adsorbent was determined by a batch method. The 20 ml solution of Cr(III) 1.0×10⁻⁸ M in pH 5.0 was transferred in to a separating funnel and 3 g adsorbent was added. The separating funnel was shaken vigorously for 30 min. Concentration of Cr in the filtrate was determined according to calibration curve data and then adsorbed amount of Cr was calculated. The retention capacity (mg adsorbed Cr/ g adsorbent) was obtained to be 0.1672 mg g⁻¹ of adsorbent or 2.01 mg l⁻¹ of ligand.

3.4. Calibration graph, reproducibility and detection limit

A series of standard solutions of Cr(III) were treated under the above mentioned optimized experimental conditions. Cr concentration can be determined in the range of 4.2×10⁻⁹ to 2.3×10⁻⁸ M with linear equation; ΔA = 0.00078×C+ 0.0056 and regression coefficient of r² = 0.9988 (ΔA is absorbance signal after preconcentration and C is molar concentration of Cr×106). The experimental limit of detection is 1.42×10⁻¹⁰ M (S/N =3). The relative standard deviation (R.S.D.%) for 10 replicate measurements of 5.0×10⁻⁹, 1.0×10⁻⁸, 1.0×10⁻⁷, 3.0×10⁻⁶ and 1.0×10⁻⁵ M of Cr(III) were 3.04, 2.95, 2.11, 3.12 and 1.90%, respectively.

3.5. Influence of foreign ions

The influence of contaminant species presented in various samples on the determination of 5.0×10⁻⁸ M, Cr(III) was investigated. The tolerance limit was defined as the concentration of added ions, causing a relative error less than 3% (Table 1). Some metal cations can be adsorbed on microcrystalline naphthalene at different pH values. This proposed adsorbent is not only able to remove anions of the Cr(III) solution but also can decrease the interference of some cations. Some of important ions that can be found in the real samples with Cr(III) such as Sn⁺², Hg⁺², Cd⁺², Co⁺², Ca⁺², Pb⁺² and Tl⁺¹ do not have any interference on the determination of Cr(III). Al and Fe can be troublesome in the determination procedure but with preconcentration their interference decreases.

The reported method is selective and simple and it has excellent capacity factor. Among other mentioned methods in Table 2 stripping voltammetry has a good sensitivity but it needs expensive apparatus and needs the operator to be skillful. Conventional solvent extractions are not sensitive enough and they consume a large amount of solvent. Also most of extracting solvents are toxic and volatile. On the basis of the results obtained from the Cr(III) standards, the recommended preconcentration method has been successfully applied prior to spectrophotometric determination of low values of Cr in the tap water(Tehran, taken after 10 min operation of the tap), rain water(Tehran, 22 January, 2013) samples. The analysis was performed by using the standard addition technique. The results are summarized in Table 3. Good recoveries in all samples were obtained. This method was reliable through comparing with eachother[22-36].

4. Conclusion

Solid–liquid extraction with microcrystalline naphthalene is an effective separation and preconcentration technique for trace elements. The method has the advantages of being simple, inexpensive and selective. This proposed preconcentration method has a high enrichment factor (100) which develops possibility of determining concentration
levels as low as sub micro amounts of Cr with eliminating the interference of some diverse ions. The selected determination procedure (after preconcentration) is convenient, sensitive and fairly selective.
